

INDIVIDUAL PROJECT REPORT

Kis Hair Melbourne Booking & Scheduling System

1. Executive Summary (max 1 page)

The Australian hair and beauty services sector is constantly experiencing a massive digital shift, with mobile booking apps as the first customer-facing solution in the salons and stylists industry. In a move to make the industry worth about AUD 7.5 billion as of 2025, modernize customer interaction and simplify the process of making appointments (IBISWorld 2025), Kis Hair Melbourne, a well-established hairdressing salon with its operations based at Shop 4/250 Spencer Street in the CBD of Melbourne, recently introduced a mobile appointment booking application which operates off the MaBa platform.

This report is a detailed business systems analysis of the Kis Hair Melbourne booking system using an Information Systems perspective, its present features, user interface design, and automated business processes based on industry-recommended UML modeling. It includes activity diagrams, use case model, class structures, and state machine behavior to nuance out a complete technical and business insight into the system architecture and operational workflows.

The system overcomes a variety of operational problems inherent to the traditional phone-based appointment management system: the removal of booking access barriers due to the 24/7 ability to self-service, reduction of information asymmetry due to transparent stylist profiling and customer reviews, real-time calendar visibility, and automated communication processes. The findings confirm that automated appointment reminders can lower no-show rates compared to manual systems (Ulloa-Perez 2022), directly affecting the efficiency of operation and revenue protection.

Yet, a critical gap analysis shows that it has a serious competitive disadvantage: there are no effective mechanisms of payment authorization capture and cancellation policy. According to industry research, the average no-show rate for appointments in service-based companies is 23% across various contexts, including healthcare (Dantas et al. 2018). Additionally, data from beauty salons demonstrates an average no-show rate of 10-30% without protective measures (EasyWeek 2025; Dashboard Beauty 2024). This equals about AUD 67,000 in yearly lost revenue of an average salon business (SalonBiz Software 2024). The most popular competitive platforms, such as Treatwell, Booksy, and Fresha, have implemented card-on-file solutions with automated cancellation fees as the standard functionality of the industry, which introduced customer expectation displays and secured business revenues against commitment abandonment.

The payment authorization capture mechanism suggested to be implemented in this report is built into the booking flow, and the customer is required to input payment card credentials during the last step of the booking as a prerequisite to booking confirmation. The improvement would allow the implementation of a configurable cancellation policy, the processing of late cancellations, and automation of the no-show charges, placing the Kis Hair digital platform at the competitive level with industry standards and ensuring the full preservation of revenue flows and greater responsibility of customers towards their commitment. This analysis shows how the functionality can fit into the existing use case architectures and bring some quantifiable business value by minimizing revenue leakage and increasing operational sustainability.

2. Business Case

2.1 Industry Background: Hair & Beauty Services in Melbourne

The hairdressing and beauty services market in Australia is a large economic sector with an estimated value of AUD \$7.5 billion in 2025 and with a competitive environment of more than 33,500 businesses operating in the country (IBISWorld 2025). This is an established industry that is undergoing transformative forces due to changing consumer demands, technological shock, and growing competition with both luxury service providers and low-end competitors. The industry has a low growth trend, with a forecast of 1.7% per year up to 2025-26, disguising the underlying operating issues, such as unstable consumer confidence, rising wages trends that make up the largest cost of operations, and the ongoing market share loss to do-it-yourself solutions via e-commerce retail platforms (IBISWorld 2025).

The digital transformation has become a strategic necessity to survive and competitive distinction in this labour-intensive traditional service sector. According to studies conducted by Fortune Business Insights (2024), the markets of salon services are getting digitized more rapidly all over the world, as online booking of appointments, diagnostic devices using artificial intelligence, and mobile consultation platforms are radically changing the paradigms of customer acquisition and retention. The implementation of digital booking infrastructure has proven to have an effect on the operation metrics, as online appointment reminders decreased the number of no-shows by 29% relative to traditional phone-based booking systems (SalonBiz Software 2024). The change in technology is indicative of the larger shifts in consumer behaviour, as 36.1% of cosmetics are sold online as of 2021, indicating that customers are comfortable with beauty services transactions mediated by technology (Accumulate Australia 2024).

The high population density, particularly in Melbourne, as the capital of Victoria, with the concentrated demographics representing the fashion-conscious, digitally-native consumers with the

discretionary spending ability, aggravates the competitive landscape among the salon operators. The premium positioning of the city in the center of business areas requires that the division of high operational expenses is compensated by the maximum use of appointment inventories, and revenue optimization through technological efficiency is not just beneficial but becomes an economic necessity due to sustainability.

2.2 Company Background: Kis Hair Melbourne

Kis Hair Melbourne has 3 flagship outlets in Melbourne that are strategically located in the busiest commuter areas in the CBD. The place will enable the salon to attract a wide range of customers, such as office workers, university students, short-stay visitors, and local residents, and enjoy the benefits of predictable weekday walk-ins and appointment-based traffic. The working days and hours of the salon, usually up to 7.00 PM on most working days of the week, point to a deliberate corroboration with the time schedule of professionals located in the central Melbourne area and in need of the salon to provide flexibility in making pre-work, lunch-hour, and post-work bookings. Slightly shortened closing hours during the weekend also indicate a service pattern that is dependent on foot-traffic dynamics specific to the CBD retailing setting.

The Kis Hair Melbourne is based on a multi-tiered, multi-stylist service delivery model, featuring a list of stylists with different degrees of seniority, price ranges, and client base. Such a strategy is reflective of standard industry practice within metro salons, where differentiated stylists can contribute to market segmentation so that the business can serve:

- Clients who are cost-conscious and choose junior or mid-level stylists and
- High-end customers, who value knowledge, technical colouring expertise, or the reputation of a stylist, and can afford higher prices.

Customer sentiment (based on online reviews) is favorable to make Kis Hair a reputable mid-tier salon; the ratings are usually in the 4.3-4.5 star range on various review sites. These scores indicate high-level service delivery and customer satisfaction, especially in men's haircutting, colouring, and chemical treatments. Nevertheless, the Melbourne CBD hair industry is a competitive one, with a large number of boutique barber studios, modern Korean/Japanese-style salons, and high-quality brand salons operating, which places a continuous strain on the need to innovate digitally and maintain the quality of services.

The service offering of Kis Hair is wide with a range of high-demand services, which include: Men Haircuts (fade, restyle, dry cut, roots retouch), Women Haircuts and Blow-Wave Styling, Hair Colouring (full colour, balayage, foils, roots retouch), Perms, Rebonding, and Keratin Straightening Treatments.

The trends in pricing as seen based on the posts by public client and app listing show that Kis Hair has a mid-range price range that is above the cheap barbershop or express salon but below the high-end boutique studio in the premium areas of Melbourne. The salon places emphasis on high-margin technical services, including rebonding, perms, and advanced colouring, which have to be certified and take longer periods of time.

The salon has shown an evident digital strategic consciousness by implementing a mobile-based booking service, enabled by the MaBa scheduling system. Such a rollout denotes a strategic investment in front office digital capability, which will put Kis Hair in line with the wider industry move toward self-service appointment systems, automated reminders, and less manual front-desk workload. Nevertheless, the existing system, as we will see below, has significant functional limitations, the most important of which are the inability to safely gather and store customer card information to charge late cancellations or no-show fees, which other competing platforms like Timely, Fresha and Square already normalise. This lapse diminishes the capacity of Kis Hair to defend revenue, cancellation policies and integrity of appointments in times of peak operation.

On the whole, the present digital and operational standing of Kis Hair Melbourne shows a high level of alignment with the expectations of an urban, high-volume salon - yet, also shows strategic points where a focus improvement would lead to a higher level of customer experience and increased protection of revenue and more efficient use of the workforce.

2.3 Services / Problems the System Addresses

The Kis Hair mobile booking system disposes of several operational inefficiencies depicted in the traditional models of appointment management that defined the pre-digital salon industry:

Temporal Access Constraints Removal: The phone-based booking systems limit the appointment scheduling process to the hours that the business is in operation and has staff to answer the phone, take requests, and manually enter the reservation details into the paper diaries or simplified digital calendars. This model artificially divides those customers whose schedules do not suit, especially the professionals who cannot make personal calls during their working hours. The mobile application (Appendix A, B) offers 24/7 self-service booking, eliminating the temporal constraint of the customer acquiring funnel and widening the salon useful booking window beyond the limiting 9-hour a day operational scope to 168 hours a week.

Reduction of Information Asymmetry: The conventional salon selection mechanisms provide little information about the expertise, specialisation, or history of customer satisfaction of the service providers before the first time interaction of the customer. The existing system applies holistic stylist profiling (Appendix I), where professional portfolios can be viewed in the form of work sample

images, customer ratings that have been integrated over several appointments, and confirmed review information with photographic evidence (Appendix G). This transparency mechanism lowers the amount of perceived risk by the customers in their selection of service providers, which ideally leads to a higher conversion rate between browsing and confirmed booking behaviour (service provider) due to the ability to make informed decisions based on personal preferences and needs.

Real-Time Visibility Calendar Optimization: Manual appointment coordination induces scheduling inefficiencies in terms of information lag--stylists are not sure of the workload each day until customers call, and customers are not sure of slots available as a result of not identifying available slots without a telephonic search, creating mutual search costs. The system slot filtering feature (which can be seen in the booking flow, Appendix D) also displays real-time availability depending on the requirements of service duration, the specific schedules of the stylist, and the current commitment inventory, allowing for setting the calendar density to its highest possible value with minimum client search effort.

Group Booking Accommodation: The system allows multiple-guest booking under a single transaction management (mentioned in Activity Diagram, Section 3), which is tasked with serving family groups, couples, or friend groups aiming to obtain the same service at the same time. The capability has improved the average transaction value by enabling volumetric booking as well as minimizing the complexity of coordination for the customer handling multi-party scheduling.

Communication Automation and Service Recovery: This will be integrated with notification service providers (as seen in system architecture, Appendix document) to provide automated delivery of appointment confirmation through SMS and email, as well as pre-appointment reminder messages. Automated reminders minimize no-show rates and have a direct impact on revenue and better utilization of stylists. The system also preserves the appointment status tracking by category--Upcoming, Finished, and Cancelled (Appendix B, H), bringing customers full visibility of booking history and allowing rebooking in the future based on historical data of service preferences.

Digital Payment Infrastructure Foundation: The application provides the technical capacity to process digital payments, which is reflected in purchase history transaction records (Appendix F) showing the cost of the services and timestamps to create a form of infrastructure that will enable the possible future execution of more advanced payment options such as deposits, prepayment, or commitments.

2.4 Opportunities & Limitations of the System

Based on the digital platform infrastructure deployed by Kis Hair, the foundational capabilities are established that underlie several business value addition opportunities in line with the current industry best practices and customer expectation development:

Data-driven Business Intelligence: The system creates structured information that entails appointment trends, service trends, stylist performance differentials, peak demand times, and customer lifecycle behaviour. Although the existing implementation is deemed to be dedicated to the processing of operational transactions, this data asset still allows for conducting advanced analytics such as demand forecasting to plan inventory, optimize stylist allocation, design targeted marketing campaigns according to customer profile segments, and conduct dynamic pricing that reacts to capacity utilization. A study by Future Market Insights (2025) also states that data analytics are one of the key competitive differentiators in the market of salon services, allowing making decisions in management based on evidence, rather than intuition.

Customer Relationship Management and Loyalty Cultivation: The membership feature of the platform (Appendix C, E) provides the platform with infrastructure towards the implementation of loyalty programs, but with zero active memberships, indicative of unfinished feature implementation. Properly implemented loyalty programs have proven to enhance retention among customers - studies show nearly 60 percent of the total salon revenue comes from customer loyalty, with the satisfied clientele being far less likely to fail to attend a scheduled appointment (SalonBiz Software 2024). The current point system and purchase history tracking offer technical conditions to operationalize the reward program that might facilitate rebooking rates beyond the industry average rates of 45-60% (SalonIQ 2024).

Multi-Location Scalability Architecture: The Other locations navigation element of the application (Appendix A) shows that even in case of franchise or branch expansion, the architecture was designed accordingly. The centralized online platform facilitates uniformity of customer experience in all locations, centralized customer profile management, and cross-location transferability of appointments, eliminating geographic barriers to business growth, as well as brand coherence.

Critical Revenue Protection Gap: Despite these areas of opportunity, a deep-seated competitive analysis shows that there exists a major gap in the economic value proposition of the system. A study by Dantas et al. (2018) records that no-show rates at the appointment in service-based industries are 23% on average and are sensitive to demographic variables, the time interval between booking and appointment, and no-show history. Data available specifically to beauty and salon services shows that the rates of no-show are between 10-30 per cent without protective interventions (EasyWeek 2025; Dashboard Beauty 2024), which translates to an annual revenue lost of about AUD 67,000 in case of average salon operations (SalonBiz Software 2024).

The card-on-file systems with automated cancellation fee enforcement are the functions that leading competitive platforms such as Treatwell, Booksy, and Fresha have implemented as industry standards. The systems intercept payment card details during the booking process, create distinct cancellation policy periods (usually 24-48 hours before appointment), and automatically charge unresponsive or cancellable clients when they miss appointments or cancel them outside of policy limits. The implementation of Treatwell enables salon operators to set cancellation windows of between 3-48 hours depending on the needs of their business, and prepaid customers fail to get their money back due to a late cancellation. The no-show protection offered at Booksy allows the salons to charge the cancellation fee and keep card-on-file when a booking is made.

The lack of similar functionality in the Kis Hair system has several negative effects:

- (1) No-show inventory wastes that resulted in revenue leaks without a compensatory fee;
- (2) Stylist wasting time producing no revenue when the appointment block was held, and instead of servicing other customers, could have been used to service other customers.
- (3) Customer behaviour reinforcement by the lack of a monetary penalty for commitment abandonment;
- (4) Competitive disadvantage with respect to other salon operators, which provide the same services with high commitment accountability mechanisms;
- (5) The inability to introduce deposit requirements on high-value services like chemical treatments that need high-value products inventory allocation.

This is especially relevant considering the CBD location the salon has and the high occupancy rates in the area where the salon is situated, and the target population of professionals who are unpredictable in their schedules. The following parts of this analysis will show how variation of this shortcoming by payment authorization capture and policy enforcement solutions would make the system more valuable, competitively positioned, and operationally sustainable, as well as compliant with the accepted industry practice standards and customer expectations informed by experience with other booking systems.

3. Activity Diagram (5 marks)

3.1 Diagram Presentation

3.2 Understanding the Booking Journey

The activity diagram depicts the process by which a client makes an appointment with Kis Hair Melbourne, and it indicates the steps a customer goes through, beginning with opening the booking page until the moment the customer is accorded a confirmation (Figure 1). The diagram consists of four vertical lanes known as "swimlanes," each of which represents a different participant: the Client (customer), the Booking UI (mobile app interface), the Kis Hair System (backend computer system), and the Notification Service Provider (external service that manages SMS and emails).

Visualize this diagram as a map of the way in which a customer navigates the booking process. The arrow indicates the flow of actions, diamonds indicate decision nodes where decisions have to be made, and rectangles indicate specific activities to be conducted. By using this visualization, it is possible to see the areas of the process that are working well and the areas that may be improved to provide a better customer experience or operations.

3.3 The Booking Process Step-by-Step

The first step in the Journey: Once a customer opens the booking page on their mobile device, the system shows the available services and stylists automatically. The client has options to choose his or her way, either by choosing a service first (such as Men's Re-style Dry Cut at \$35) then viewing which of the stylists offers it, or by finding a favorite stylist and viewing his or her services. The options are two routes to the same destination and thus provide the customers with a choice depending on their priorities.

Creating Appointments: After the customer has selected a service and a stylist, the system narrows down time slots available to them depending on the duration of the service and the schedule of the stylist. To illustrate, one haircut that takes 25 minutes does not need to be scheduled same as a 90-minute coloring session. The customer chooses a desired date and time with the help of truly available opportunities.

Customizations: Customers have the option to add additional features before making the final decision. The diagram depicts decision points that inquire about the addition of extra service, and "Add Note?" It has optional add-ons that enable one to book more than one service at a time, place special requests such as do not make me too short, or even reserve on behalf of more than one person at the same time (group booking feature). Every addition will cause the system to re-compute overall time and pricing.

Authentication Step: A crucial decision point regards the question Sign In Yet? Customers who already have an account can sign in with email or third-party applications such as Google or Facebook, or create a new account. Users who do not want to create accounts remain as guests by just giving the contact information (name, phone, email). Such a two-fold strategy will provide convenience to beginners and more features to repeat clients.

Modification Opportunities: When customers desire to make alterations in some form such as different time, stylist or service, the diagram indicates that the process re loops back to previous phases without any loss of progress. These modify booking (drawn with arrows marked [Change Time Slot], [Change Stylish], [Change Service]) allow customers not to repeat the whole process with minor changes.

System Processing: Once the customer approves of this request by clicking on the button Book Now, several events occur concurrently in the background. The system will produce the unique booking reference number, generate the official booking record in the database, reserve the time slot of the stylist to avoid double-booking, update the profile of the customer, and make the appointment in the salon calendar.

Communication and Confirmation: Concurrently with record creation, the Notification Service Provider provides immediate confirmation through the SMS and email with all the details of the appointment and the reference number. The system will also have an automated reminder that will be sent 24-48 hours before the appointment date so that it can help reduce the no-show by reminding the customer. In the meantime, the stylist calendar is updated and the blocked time and customer data are displayed.

4. Overall Use Case Diagram

4.1 Diagram Presentation

4.2 Services offered to each user

Clients (guests and members)

Clients can discover and book services end-to-end. Discovery includes **View Location** and **Choose Location**, **View Service Category** and **Choose Service Category**, **View Service**, **View Stylish**, and **View Stylish Profile/Review** with the option to **Write Review/Feedback** after appointments. Once a service and stylist are chosen, clients **Choose Appointment Time** and **View Availability**, then **Book Appointment**. During booking they may **Add Extra Service**, **Add Note**, or **Create Group Appointment** (modeled as extensions), and the system **Reserve Slot**, **Create Booking Reference Number**, **Create Booking**, **Create Calendar Event**, and issue confirmations. Clients can also **Modify Booking**, **Reschedule Booking**, **Cancel Booking**, **View Past Booking**, and **View Receipt**. Members additionally **Create Profile**, **Login/Register**, **Apply Promotion**, **Redeem Loyalty Point**, and **Track Loyalty Point**.

Stylists

Stylists inherits all use case from the Senior Staff but focus on operational scheduling and profile quality. They can **View Booking Calendar**, **Change Personal Availability**, **View Profile**, and maintain their professional presence through **Create Stylish Profile** and **Change Stylish Profile**. These services ensure stylists' calendars align with client demand and that public information remains current and accurate.

Staff / Senior Staff (management functions)

Front-of-house staff and senior staff supervise day-to-day operations and controls. Core services include **View Booking**, **View Calendar**, and **Modify Booking**. Senior staff add governance and performance levers such as **Override Price**, **Block Date/Hour** (capacity control), and **Track Analytic Dashboard** (performance metrics and reporting). These managerial services complement stylist-level controls and enable rapid response to demand spikes or operational constraints.

Notification Service Provider (external)

This actor executes time-critical client communications: **Send Confirmation (SMS/Email)** after a booking is created, **Send Reminder** prior to the appointment, and **Send Post-Appointment Email** afterward.

5. Expanded Use Case (Detailed Use Case Diagram)

5.1 Diagram Presentation

Use case name	<i>Book Appointment</i>	
Scenerio	Online booking by client (web/mobile)	
Triggering Event	Client initiates a new booking from the booking page	
Brief Description	The client selects a service and stylist, views availability, holds a slot, and identifies themselves (as a guest or by signing in). The system then commits the booking, generates artifacts (Booking Reference), creates a Calendar Event, reserves a slot, and sends confirmations.	
Actors	Client	
Related Use Cases	Includes: - Choose Location - View Location - Choose Service - View Service - Choose Service Category - View Service Category - View Stylish - Choose Stylish - Choose Appointment Time - View Availability	Expands: - Create Group Appointment - Add Extra Service - Add Note - View Stylish Profile - Write Review/Feedback - View Stylish Review
Stakeholders	- Stylish - Senior Staff - Notification Provider	
Pre-conditions	- Booking system is online, service catalog and stylist rosters are up-to-date. - Internet connectivity is available	
Post-conditions	- A confirmed booking record exists with reference ID - The stylist's calendar is updated - A receipt and Post-appointment confirmation are sent to the client.	

Flow of activities	Actor	System
	1. Client opens the booking page	
		2. Display service categories
	3. Client selects a service category	
		4. Show service details and price
	5. Select a service	
		6. Show stylish available for the service.
	7. Select a stylish	
		8. Display stylist availability schedule
	9. Client selects a date and time	
	10. Client signs in or continues as guest	
		11. Validate identity credentials or capture contact info
	12. Client adds extra service (optional)	
		13. Recalculate total price and duration.
	14. Client enters notes or	

	requests (optional)	
		15. Attach note to temporary booking record
	16. Client add extra guest (optional)	
		17. Recalculate total price and duration.
	18. Client reviews summary and accepts policy.	
		19. Display Confirm Booking option
	20. Client clicks “Confirm Booking”	
		21. Commit Booking: create record, generate Booking Reference, block the slot and create Calendar Event.
		22. Send confirmation SMS and email with Booking Reference and Receipt.
	23. Client views confirmation screen	
Exception Conditions	1-21: If the Slot expires during selection, show an alert and release the hold; return to the availability screen. 9: If Sign-in fails, the customer can Prompt retry or continue as a guest.	

The extended use case diagram of “Book Appointment” gives a step-by-step analysis of the process of creating an appointment as seen through the eyes of a client using Kis Hair Melbourne booking system. Although the overall use case diagram shows the general functional capabilities of the system, this extended version addresses the series of interactions that would be necessary to successfully create a confirmed booking, making system behaviour and user actions an easy articulation.

The booking procedure starts when a customer enters the reservation platform via the internet or mobile platform. The system will offer immediate availability of service categories and allow the user to browse according to his/her preferences. Clients can browse the categories, look at particular services, analyze the prices, and read about stylists to make a commitment to their choices. After the selection of a service, the system shows the stylists available to carry out the service, and their respective availability schedule.

Once a service and a stylist are selected, the client then picks an appropriate appointment date and time that is according to real-time availability. The system will then ask the client to identify themselves either through signing in to an existing account or proceeding as a guest with a bare minimum of contact information. Extra value-added features like adding additional services, adding personal notes, or additional people as the client can tailor their appointment. All these additions update dynamically the overall time of the appointment and the end cost so that there is accuracy before confirmation.

After making all selections and optional add-ons, the system also displays a complete booking overview which includes details of the service, choice of a stylist, time, and the salon policy. When the client presses the Confirm Booking button, the system carries out a few basic functions: it adds an official booking record, it generates a specific booking reference number, it blocks the chosen slot in the calendar of the stylist to avoid being double-booked and it forms the event in the calendar. The confirmation message and receipt are delivered through emails and SMS immediately after this by the Notification Service Provider.

Exception handling provides robustness of the process. In the case of time slot expiration at any phase by system update or overlapping reservations, the system will alert the user and take him back to the availability screen. In the same way, on a sign-in failure caused by identity verification, the system allows a re-try, or one can use a guest booking.

Altogether, this broadened use case has shown how the booking system can be used to organize a variety of interrelated services to present a highly smooth and efficient appointment experience to customers and keep the operational precision of the salon.

6. Class Diagram

6.1 Diagram Presentation

Kis Hair Booking System

6.2 Relationships

The class diagram depicts the essence of the structural aspects of the Kis Hair Melbourne booking system and the connections between the key classes. Each of the classes is a major entity in the appointment lifecycle and the associations outline how the entities are dependent on each other or interact.

The model has the Booking class at its centre and this is a confirmed or pending appointment made in the system. This diagram indicates that a Client makes bookings, which is a 1-to-many relationship. This implies that every one of the bookings has at most one client, although a client can have 0 or many bookings. It is not possible in the reverse scenario: no booking is possible without a client to make and that any appointment should be associated with a customer.

Every booking is also associated with one to many Service. This is indicative of the fact that every appointment is associated with at least one or numerous service (e.g., haircut and colouring).

The relationship between Booking and Stylish (stylist) is not much different: a booking should specify at least 1 stylist and a stylist may have none or numerous bookings. This is in line with the salon scheduling where the stylist has to allocate various appointments in a day. The relationship validates the fact that each booking should be assigned to at least one stylist.

The Location class is related to Stylish with a many to many and this implies that a stylist may be employed in more than one location and a location may employ many stylists. This system enables the cases when Kis Hair may have many branches or provide selected services at special places.

Profile class relates to both Client and Stylish which are related through one-to-one association (Can have 1). This demonstrates that profiles contain individualised data of customers and stylists (the likes, history, or professional details) and none of the users will share a profile record.

A CalendarEvent is linked to the creation of a booking and scheduling. The diagram indicates that the documentation of the 1 calendar event is generated by bookings and that the calendar event is connected to the 1 booking. This one to one relationship means that each appointment will be a single calendar record in the salon schedule, which will not be duplicated or booked twice. Owing to the fact that CalendarEvent also communicates with Stylish (through system processes), it provides synchronisation of availability of the stylist with the client bookings.

In general, this class diagram creates a clear structural background: the interaction between clients and stylists is carried out through bookings, the interactions between bookings and services and calendar events, and the insights of the system are obtained on the basis of booking data to make the business decisions.

7. State Machine Diagram

7.1 Diagram Presentation

Booking's State Machine Diagram

7.2 Relationships

The **State Machine Diagram** represents the whole lifecycle of a **Booking** object in the Kis Hair Melbourne system, in such a way that the creation and completion of an appointment passes through different states of its operation. It gives a dynamic view of the system behaviour that supplements the static class diagram by showing the responsiveness of a booking in relation to user actions, system events, time conditions, and policy requirements.

The lifecycle starts in the **Initiating** composite state where the client undergoes the necessary selection processes as needed to put up a valid appointment request. This involves the choice of the service, stylist and schedule, identity verification and consultation of the booking information. After the client confirms, the system switches to the internal **Confirming** state, and key processes take place, which include the creation of the booking record, the establishment of a unique reference number, the creation of the salon calendar event, and the change in the availability of the stylists. A consumer finally sends the booking to the **Confirmed** composite state.

The state machine within Confirmed is further divided into two parallel, which are **Client Communication and Resource Calendar**. These operate concurrently to ensure that there is a congruency between what the client views and operational dependency. Afterward, the confirmation email and SMS are sent by the communication region and thereafter a reminder is scheduled. At the same time, the calendar area excludes the time slot of the stylist so that it is not booked twice and the internal scheduling system in the salon is updated. The history state (H) means that when the booking re-enters **Confirmed** on modification it re-enters the appropriate sub-state without restarting the entire process.

After the completion of the two regions to their final states, the booking is still in **Ready for Service** awaiting the appointment day. The system can change to **Cancelled** in case the client cancels, or **Amending** in case the client makes changes to any of the core elements (service, stylist or time). The state of amending itself is a composite state that has decision branches of any type of change. The system re-computes the availability and pricing and re-validates the new booking before returning, via deep history, to the appropriate point in the Confirmed state.

When the appointment time comes, the booking will be transferred to **In Service** when the client reports at the salon. Once the service has been finished by the stylist, the booking is transferred to **Completed** and after appointment services like receipts and feedback are sent.

The state machine then provides an event-based, detailed perspective of the behaviour of bookings, providing operational integrity, the logic behind the modification, and giving the communications, scheduling and service delivery a perfect fit during the booking life cycle.

8. UI Design Analysis

Theoretical Framework Evaluation quality of user interface design is assessed using known usability evaluation techniques, most of which are based on heuristic evaluation systems first introduced by Nielsen and Molich (1990) and later tested empirically (Nielsen 1994). The approach facilitates the identification of usability issues systematically by reviewing them with experts using a set of design principles without any large-scale user testing infrastructure (Yanez Gomez et al. 2014). In the context of mobile-specific applications, general heuristics designed to work well on desktops will have to be modified to meet special constraints such as a small screen size, the use of touch-sensitive input and output, and contextual usage behavior associated with the use of mobile devices (Punchoojit and Lawson 2017). The Kis Hair Melbourne booking application will have to be evaluated in relation to several aspects' effectiveness: visual hierarchy and information architecture, consistency and compliance with mobile platform norms, interaction design suitability to touch interfaces, and overall compatibility with the modern philosophy of mobile (Lashin et al. 2021; Darmawan et al. 2022).

8.1 Commendable Design Elements

Visual Consistency and Brand Coherence: The application exhibits a uniform use of a consistent visual language that uses pink and white as the color scheme (which is visible throughout Appendices A through J) that creating a strong brand identity without compromising the sufficient contrast ratio to read. This compliance with the principles of visual standardization facilitates the recognition of users and the decrement of cognitive load during navigation (Lashin et al. 2021). The linear treatment of the primary brand color (vibrant pink) with the interactive elements (highlighted with the navigation) and call-to-action buttons form a predictable affordance cueing, allowing users to quickly locate actionable interface elements, which is a key principle of usability applied and confirmed through the research of mobile interfaces (Punchoojit and Lawson 2017).

Information Architecture Clarity: The overall top-level navigation structure using the tabbed organization structure in the application (Home, Appointments, Profile visible in Appendix A, B, E) demonstrates the proper choice of the mobile information architecture patterns. Tabbed navigation is used to allow easy context-switching between major functional areas and ensure uninterrupted accessibility - this style is especially well-suited to apps providing different but heavily-visited categories of tasks (Yanez Gomez et al. 2014). The low-tab bar placement is a type of mobile ergonomic best practice, placing primary navigation in comfortable thumb-reach areas to be operated with one hand, which will resolve the physical interplay limitations of mobile interaction behavior described in the mobile usability literature.

Good Feedback Mechanisms: The appointment status categorization system (Upcoming, Finished, Cancelled tabs in Appendix B, H) gives a good view of the system status, which fulfills the core heuristic of Nielsen about system status clarity (Nielsen and Molich 1990). The booking lifecycle stages can also be determined quickly and unambiguously by users to lessen uncertainty and facilitate informed decision-making in relation to actions of managing appointments. The use of booking confirmation numbers and timestamps (Appendix F - Purchase History) serves as an additional tool to improve the clarity of the system, as they give a clear transaction identifier that allows the customer to inquire with the customer service and verify the records.

Service Discovery Facilitation: The stylist browsing interface (Appendix I) includes the visual portfolio features, such as work sample images in combination with quantitative rating evidence, as a solution to the issue of information asymmetry in a service provider selection environment. This multi-modal presentation of information favors users with different levels of decision-making preferences - some that value the peer validation of their choice with numerical ratings, and others that value the visual style when it comes to assessment with portfolio images.

8.2 Design Deficiencies Requiring Remediation

Insufficient Visual Hierarchy in Critical Booking Flow: The booking setup screen (Appendix D) has poor visual hierarchy, especially in conveying booking summary details before actually committing. The studies show that a good visual hierarchy with size differentiation, impressive use of colors, and proper spatial placement can direct user focus to mission-critical information (Lashin et al. 2021). The existing implementation offers insufficient service selection, stylist assignment, time slot, and optional add-ons, which may be associated with booking errors due to insufficient prominence of information. Total price as a paramount factor of decision must be visually customized with font weighting, size magnification, or use of strategic color placement in such a way that the users are made conscious of the financial commitment level before confirmation.

Empty State Design Inadequacy: Various interface screens have generic "No results found" messages and a lack of specific iconography (Appendices B, C). The modern design ethics of mobile state are that blank spaces are an important chance to guide users, educate them, or prompt them to do something instead of informing them of their emptiness (Darmawan et al. 2022). The state of appointments (Appendix B) may offer practical opportunities like direct booking start buttons or training material about booking procedures. The memberships void state (Appendix C) likewise symbolizes missed prospects to convey membership offerings propositions and handle enrollments, especially considering the reported inactivity of memberships, introducing underutilization of loyalty infrastructure.

Navigation Clarity Deficiencies: The disposition of some functions within the information architecture exhibits ineffective discoverability. Access to purchase history needs navigation to Profile - Purchase History (Appendix E, F), which buries transactional records two levels deep, even though it is relevant to interactions with customer service and in financial record-keeping. The heuristic about recognition over recall proposed by Nielsen points out the reduction of the memory load by the visual presentation of options (Nielsen 1994). Critical functions such as booking history and transaction records deserve high visibility, which may be achieved by a special primary navigation tab or a high position in the current tab hierarchy.

Inconsistent Touch Target Sizing: Analysis of interactive objects shows that the size of touch targets is inconsistent. Although primary call-to-action buttons (e.g., Book now in Appendix D) seem to be correctly sized, other interactive items, such as review expansion controls and service category selectors, have smaller sizes that may appease users with motor control issues or work in mobile conditions with movement or distraction. The literature on mobile-specific heuristics stresses that the minimum size of touch targets should be 44-48 pixels in order to match the average size of a fingertip and avoid unintentional selection (Yanez Gomez et al. 2014). General audit and remedial of undersized interactive elements would improve accessibility compliance and minimize errors in interaction.

Color Contrast Insufficient in Secondary Text: The main interface text has decent contrast with backgrounds, whereas secondary informational text, such as the description of the services and metadata (timestamps and stylist names in smaller font), has a marginal contrast ratio. The accessibility guidelines set the minimum contrast ratios of 4.5:1 between normal text and 3: 1 between large text to maintain legibility under the change in visual acuity (Yanez Gomez et al. 2014). Users who use devices with poor lighting conditions- as is usually the case with mobile use- can realize lesser legibility. In systematic contrast remediation, be it text darkening or background lightening, accessibility would be enhanced without prejudice to aesthetic goals.

Feedback Mechanism Gaps in Booking Modification: The booking rescheduling policy communication and the potential consequences associated with the rescheduling are not well conveyed through the interface. The system must have the proactive ability to notify users of all valid time constraints and financial constraints to be made when they trigger an order to modify their confirmed bookings. This is a breach of the error prevention heuristic of Nielsen that highlights the responsibility of the system to prevent user errors by anticipating them by providing preemptive advice, as opposed to detecting the error as it occurs (Nielsen 1994). Clear and transparent policy communication will lessen user frustration and, therefore, enable making informed decisions aligned with the interests of users and with business operational needs.

8.3 Synthesis and Improvement Priorities

The Kis Hair Melbourne application displays the skillful implementation of the basic rules of mobile interface design, especially the visual consistency, the structure of navigation, and the organization of information. Nonetheless, obvious gaps in visual hierarchy optimization, empty state utility, and compliance with accessibility indicate that it can be refined to increase both its usability and competitiveness.

The priority remediation should consider:

- (1) visual hierarchy improvement in booking confirmation operations that place emphasis on financial commitment transparency;
- (2) state of emptiness redesigning void interfaces into actionable engagement opportunities;
- (3) accessibility audit of contrast ratios and touch targets size; and
- (4) active policy outreach in booking adjustment processes.

These enhancements are specific to the principles of established mobile usability principles and respond to business requirements such as conversion optimization, improvement of customer satisfaction, and efficiency in operations.

9. Strategic Improvements

9.1 Identified System Enhancement: Secure Payment Authorization Capture Mechanism

The most urgent functional improvement that should be implemented is the introduction of secure payment card authorization capture into the appointment confirmation process. Such a change deals with one of the inherent business weaknesses that lack any means of financial commitment to enforce cancellation policy adherence and accountability in the face of no-shows. The suggested improvement involves payment card credential collection as the final processing of the booking process, which takes place after service selection, stylists assignment, time slot confirmation, and identity authentication but prior to the final booking commitment generation.

Its implementation uses industry standard tokenization protocols of payment tokens upholding Payment Card Industry Data Security Standard (PCI-DSS) compliance via third-party payment gateway integration, as opposed to direct credential storage, reducing security liability, and providing the subsequent authorization of a transaction. The change in system architecture needs:

- (1) implementation of secure payment form interface into payment confirmation workflow;

- (2) formation of merchant account relations with payment processing intermediaries;
- (3) setup of automated charge authorization logic which is activated by specified policy violation conditions; and
- (4) policy communication interfaces where there is visibility to the customer of the terms of commitment before credential submission.

9.2 Theoretical Foundation: Behavioral Economics and Commitment Device Theory

The rationale behind the proposed improvement is theoretical in nature based on the behavioral economics of literature on commitment devices, voluntary mechanisms individuals use to limit their future options in the service of long-term goals despite susceptibility to short-term temptations (Rogers et al. 2014). Commitment devices solve the question of time-inconsistency whereby actors show preference inversion between planning and execution periods: when customers make a reservation, they are actually willing to attend an appointment they had planned, but once the opportunity comes and motivation declines (Derksen et al. 2024).

According to Rogers et al. (2014), two basic types of commitment devices include hard commitment mechanisms, which enforce a tangible financial punishment in case of non-compliance, and soft commitment mechanisms, which use a psychological or reputational penalty. The payment authorization capture with automatic charge feature is a middle ground- the card-on-file condition is a soft commitment by the sheer presence (psychological consciousness of the possible charge), whereas the execution of a charge by violation of policy is a hard commitment enforcement (real financial penalty).

Empirical studies have shown that commitment devices are effective in various areas of health behavior, such as medication adherence, smoking cessation, and attendance at appointments. According to Fanaroff et al. (2023), commitment pledges are especially effective in enhancing the rate of behavioral compliance, with financial commitment mechanisms being especially effective when used together with automated reminders. In the context of healthcare appointments, Derksen et al. (2024) record that the mechanism of advancing commitment enhances the attendance rates by minimizing the impulse to cancel or abandon the appointment, confirming its relevance to appointment-based services outside the healthcare sector.

9.3 Empirical Evidence: No-Show Economic Impact and Prevention Efficacy

Appointment non-attendance is a major economic cost in the service-based sectors. Dantas et al. (2018) undertook a systematic literature review that included 105 studies in various medical fields and found an average no-show rate of 23 percent with a significant difference according to demographic characteristics, the lead time to appointments, and a previous history of no-shows. According to industry-specific data on salon and beauty services, similar or higher rates of 10-30% without protective interventions are observed. According to Parikh et al. (2010), no-shows cause ripple effects such as revenue loss, low efficiency on the part of the provider, high costs of operation due to idle resources, and lower accessibility of waitlisted clients wishing to be able to get an appointment.

The financial penalty mechanisms are proven to be effective in decreasing the occurrence of no-shows. Leibner et al. (2023) compare two types of no-show mitigation policies in the Israeli healthcare system: on-booking co-payment deposits and on-booking co-payment deposits, which are paid upfront and refunded on no-show, and on-non-attendance paid a fine is paid. They find that upfront payment models have better compliance due to reduced collection infrastructure (payment is made at time of booking, eliminating hard-to-collect post-facto recovery) and increased salience (financial commitment creates a sense of psychological accountability).

The literature on revenue management records the imperatives of optimization of capacity in an appointment-based service enterprise. According to Campos et al. (2025), the service industries with fixed capacity, perishable inventory (time slots are not stockable), uncertain demand, and a high fixed cost structure demand advanced demand management to achieve maximum revenue per unit of available capacity. Restaurant revenue management studies have underlined that to achieve optimal capacity utilization, both table occupancy optimization as well as service duration management are required principles that are equally applicable to salon work, where the stylist's time is the perishable inventory that should be taken care of.

9.4 Business Value Proposition: Multi-Dimensional Impact Analysis

The safe payment authorization capture brings value to four mutually enhancing dimensions, namely revenue protection, operational efficiency, customer behavior and competitive positioning.

Revenue Protection and Capture Enhancement: No-shows cause a direct loss of revenue in terms of unused capacity and an indirect loss opportunity in terms of alternative bookings missed. Salon 40 stylists-hours per week with an average no-show transaction value of AUD 35 would lose salon no-show revenue of approximately AUD 14,560 ($20 \times 40 \times 52 \times 35$) at documented industry no-show rates of 20% (conservative estimate: 10-30-range). Leakage is recaptured by payment authorization which allows the cancellation fee of 50-100 percent of the service value based on time of cancellation. There is also the psychological deterrent effect which minimizes real no-show rates. It is recorded in

Leibner et al. (2023) that early payment prerequisites diminish no-show by creating a sense of financial responsibility and indicate a possible 30-50 percent decrease in default no-show rates. Experiencing combined revenue recovery by collection of fees and behavioral deterrence effect on average has an estimated annual value of AUD 8,000-12,000 of single-location operation.

Improvement in Operational Efficiency and Capacity Utilization: In addition to financial recovery, no-show decrease improves operational measures such as utilization rates of stylists, schedule predictability, and efficiency of resources allocation. According to Campos et al. (2025), service capacity is perishable inventory: empty appointment slots produce zero marginal revenue irrespective of the absorption of fixed cost. Higher attendance reliability allows more aggressive time optimization of the schedule, lessening protective buffer time between appointments and more daily service transactions. Also, lower no-show uncertainty leads to higher staff satisfaction via predictability of income (important with commission or productivity-based pay systems typical of the salon sector) and predictable workload.

Customer Commitment Quality Enhancement: Payment Authorization Requirement. Customers who are ready to submit payment credentials indicate greater true interest and chances of commitment than those who do not have to submit any payment credentials. This self-selection effect enhances the quality of average customers by screening non-essential or window dressing bookings that are unlikely to translate into actual attendance. As Rogers et al. (2014) record, commitment mechanisms can eliminate defection among already-committed individuals as well as filter out less-committed individuals during enrollment, creating a two-fold payoff of enhanced compliance among enrollees and increased seriousness among initial participants.

Competitive Market Alignment and Customer Expectation Satisfaction: The improvement brings Kis Hair platform to the point of conforming to the best industry standard practices. Analysis of competitive salon booking web sites such as Treatwell, Booksy, Fresha, and Timely all indicate the widespread application of card-on-file where a cancellation policy can be operated. Experiences of customer booking processes across the service categories such as medical appointments, restaurant reservations, hotel bookings and fitness classes are increasingly being determined by the customer expectations as to how services are provided by requiring capture of payment credentials. Lack of this feature is an indicator of operational informality that may compromise perceived professionalism and brand credibility. On the other hand, implementation reflects care of mutual respect in customer and business time value and professionalizes the service delivery relationship.

9.5 Implementation Architecture and Policy Design Considerations

The best implementation involves a balanced policy configuration between the revenue protection goals and customer experience conservation and positioning. Leibner et al. (2023) also underline the significance of policy transparency, high-profile communication, and balanced treatment of exceptions to maintain customer relations at the expense of holding individuals accountable.

Recommended policy framework includes:

- **Cancellation notice:** 24-hour advance notice requirement to cancel penalty-free (to effect alternative booking accommodation), which is consistent with industry standard and would allow time to do so.
- **Graduated penalty scheme:** 50% value of service charge cancellation within the 24 hours; no-show (Failure to attend or cancel) charge 100%
- **Exception protocols:** Emergency situations (recorded illness, family emergency, extreme weather) should be granted penalty waiver on review by the manager with the same spirit of ensuring the goodwill without compromising the overall deterrence.
- **Communication touchpoints:** Disclosure of the policy during the booking process (prior to submission of payment credential) and confirmation email repetition and reminder notification should be included as a guarantee of informed consent.
- **High-value service conditions:** Services of over AUD \$100 (chemical treatments, multi-service packages) might be subjected to full prepayment as opposed to authorization-only due to high revenue exposure.

Security is the first consideration in technical implementation by means of Payment Card Industry compliance, with proven payment gateway providers (Stripe, Square, or PayPal) providing tokenisation services that convert sensitive card data to non-sensitive tokens stored in Kis Hair system, but not in payment gateway, to retain the actual credentials. This architecture reduces security liability, shortens the time taken to comply with regulations, and allows quick deployment using integration libraries provided by providers.

9.6 Anticipated Outcomes and Success Metrics

The quantifiable success measures under improvement evaluation are:

- **Reduction of no-show rate:** Baseline measure and post-implementation measures aimed at achieving a 30-40% reduction.
- **Revenue recovery:** Tracking of cancellation fees raised monthly, and no-show losses presumably avoided.
- **Booking conversion rate:** Tracking percentage of bookings initiated that go through the payment authorization process, finding areas of possible friction.

- **Customer satisfaction indicators:** Inclusion of questions on payment policy in the post-appointment survey to maintain the quality of the experience ensures that the quality of the experience is maintained.
- **Competitive benchmarking:** Before and after implementation comparison of customer acquisition cost and retention rate.

The improvement is a strategic capability improvement that converts the Kis Hair booking system into a tool of transactional scheduling into revenue management platform. In addition to short-term financial effects, the change exhibits operational maturity, professionalization of customer relationships, and facilities infrastructure to support future business model innovations, such as membership programs that need recurring billing functionality and package pre-purchase deals that need payment processing connectivity.

10. Integrating Improvements into Two UML Diagrams

Diagram 1: Updated Overall Use Case

The new overall use case diagram offers a coherent representation of the functional scope of the Kis Hair Melbourne booking system outlining the services to be offered to its core user bases with the introduction of a new secure payment authorization system. The underlying premise of this improvement is the fact that it reinforces the overall operation of the system because the gap that was observed with regards to cancellation fee imposition and no-show responsibility is addressed. The diagram also does not only show the interaction of user with the system, but also indicates how the new processes associated with payment logically fit in the already existing appointment working process.

The secure payment authorization feature is introduced on the point of critical service selection and booking confirmation. In this case, the cancellation and no-show policy has been introduced to the system and made available to the client so that they are aware of the terms of commitment. The system then calls the Capture Payment Authorization use case in which payment card credentials are entered by the client using a secure interface. This feature does not save sensitive card information into the system of the salon; instead, it produces a token authorization via a 3rd party payment gateway - a new participant added in this diagram. This token can be later used by the system to impose enforceable charges, where necessary, without interfering with data security.

The revised diagram also includes the policy-based financial results by including related use cases including Evaluate Cancellation Window, Charge Cancellation Fee, Detect No-Show, and Charge No-Show Fee. These processes are done on a conditional basis so that charges are charged only when policy conditions are fulfilled. The Release or Adjust Authorization use case assists with the adjustment or cancellation of adjustments that are not subject to a penalty and keep the financial holds accurate and equitable. These extensions combined result in policy enforcement being a part of the booking lifecycle.

To stylists and senior staff, they will add the use case as they can Configure Cancellation Policy and Handle Policy Exception where they ought to the client requirement. However, the system does not cancel their current functioning operations such as the ability to see bookings, update availability, and service offerings. The improved payment process does not affect these functions but, on the contrary, supports the stability of the work process by minimizing the adverse effects of non-attendance of clients.

Altogether, the revised use case diagram would illustrate how the booking system has become a system that incorporates secure financial responsibility into its project, which improves customer transparency, efficiency of operations and business sustainability.

Diagram 2: Updated Expanded Use Case Diagram

Use case name	<i>Capture Payment Authorization</i>	
Scenerio	Online booking by client (web/mobile)	
Triggering Event	Client reaches the ‘Add Card Information’ step after reviewing the booking summary and accepting the cancellation/no-show policy.	
Brief Description	The system securely collects the client’s card details and sends them to the Payment Gateway using tokenization. The gateway returns a payment token and creates an authorization hold for the configured amount (for example, a percentage of service value or a fixed fee). The booking record stores only the token and authorization metadata, not raw card data. Confirmation of successful authorization is shown to the client and logged for audit.	
Actors	Client	
Related Use Cases	Includes: - Present Cancellation/No-Show Policy - Add Card Information - Send Payment Communication - Release/Adjust Authorization - Detect No-Show - Evaluate Cancellation Window	Extend: - Charge Cancellation Fee - Charge No-Show Fee - Configure Cancellation Policy - Handle Policy Exceptions
Stakeholders	- Senior Staff - Payment Gateway - Notification Provider	
Pre-conditions	- Booking system is online and reachable - Client has selected service, stylist, and time slot, and has identified as guest or signed in - Cancellation/no-show policy has been presented and accepted	

	- Payment Gateway credentials and merchant configuration are active	
Post-conditions	Success: - Payment token and authorization hold are created and stored in the booking record (token only) - Client receives authorization confirmation notification - System is ready to proceed to Confirm Booking Failure: - No token/authorization stored, booking remains at payment step with actionable error message	
Flow of activities	Actor	System
	1. Client confirms they have read the cancellation/no-show policy.	
		2. Validate that policy acceptance is captured.
	3. Client chooses “Continue to payment”.	
		4. Render Add Card Information using PCI-compliant fields (gateway elements).
	5. Client enters card details and submits.	
		6. Validate client-side

		form, then send card data directly to Payment Gateway for tokenization (system never stores PAN).
		7. Receive payment token from gateway; create authorization hold for configured amount (policy-based).
		8. Persist token, authorization ID, amount, and expiry in booking record (no raw card data).
		9. Send authorization confirmation via Send Payment Communications.
		10. System displays “Authorization successful” to Client.
	11. Client proceeds to final booking confirmation.	
Exception Conditions	1. Card validation error (client-side) Condition: Invalid number, expiry, CVC. System response: Show inline errors, do not call gateway. 2. Policy exception (manager override) (extends)	

	Condition: Approved waiver (e.g., disability, emergency). System response: Skip or reduce hold amount, record reason, continue flow. 3. Amount mismatch after change Condition: Client changes service/stylist/time before confirming booking (price changed). System response: Void prior hold and create new hold (handled later by Release or Adjust Authorization when the change is committed). 4. Client cancels payment step Condition: Client backs out. System response: Do not capture authorization; return to review page.
--	--

The extended use case diagram of Capture Payment Authorization gives a more detailed analysis of how the new secure payment step works in the booking process that is described in Section 10.1. Although the general use case diagram depicts the relationship of this feature to the broader system, the detailed one expands the process inside the system, revealing all actions taken between the client and the system and the external services on the occasion of a payment authorization being captured. Such detail is essential in seeing how the new functionality reinforces policymaking and the reliability of operations without creating an extra layer of friction for the user.

The use case commences when the client has gone through their booking summary and agreed on the cancellation and no-show policy. Here, the system redirects the client to the Add Card Information interface that incorporates safe industry-approved payment areas. The diagram explains that card numbers are not received and stored in the system of the salon; rather, the card information is directly sent to a Payment Gateway that returns a token that depicts the card and an authorization hold is created. This will make sure that it is completely in conformity with data security standards and it will also allow the salon to enact its attendance policies.

The extended chart further reveals a sequence of included use cases, including the display of the policy, payment confirmation messages, assessment of the cancellation time, and modification of the approval value, that collaborate to offer accuracy and transparency in the entire procedure. The optional or conditional relationships represented by the extend relationships include charging a cancellation fee, charging a no-show fee, or use of policy exceptions as allowed by senior staff.

Mapping these interactions the revised expanded use case diagram shows not just the interaction of the capture of the payment authorization, but also how it interacts with other system components at various points in the lifecycle of a booking. This will allow technical and non-technical readers to learn how the new feature will fit into the current workflow, will aid in fairness and accountability, and will assist the salon in safeguarding its limited appointment capacity.
